
Alfred And Cavity The Band Apart Rar

we propose a new method for the analysis of local field potentials (lfps). the method allows to extract phase-locked features from the lfps, which do not need to be filtered. the features are represented as the relative distance of each time point from the mean phase of the lfps. the feature space consists of time points with the same phase of the lfps, rather than time points corresponding to different phases. this property allows to create a dynamic representation of the lfps, where the features are always changing. as a first step, we identified features of the lfps, extracted from the lfps of the hippocampus (ca1 and ca3) in the medial prefrontal cortex (mpfc) of rats during the active and inactive phases of the resting-state. the lfps were filtered using a bandpass filter at theta frequencies (6-12 hz), and then phase-locking features were extracted from the filtered signal. the results showed that the theta-phase locking features are higher during the inactive phase than during the active phase. also, they showed that the theta-phase locking features changed their phase during the transition from active to inactive phase, which was shown by the relative distance of the phase of the theta-phase locking features from the mean phase. thus, the method allows to detect changes in the phase of the theta-phase locking features during the transition between the active and inactive phases, in a non-stationary and nonlinear system. as a next step, we compared the theta-phase locking features between the hippocampus and the mpfc. we found that the theta-phase locking features were stronger in the mpfc than in the hippocampus, both in the active and inactive phases. the findings suggest that the mpfc has an active role in the regulation of the theta-phase locking features during the transition between the active and inactive phases of the resting-state.
